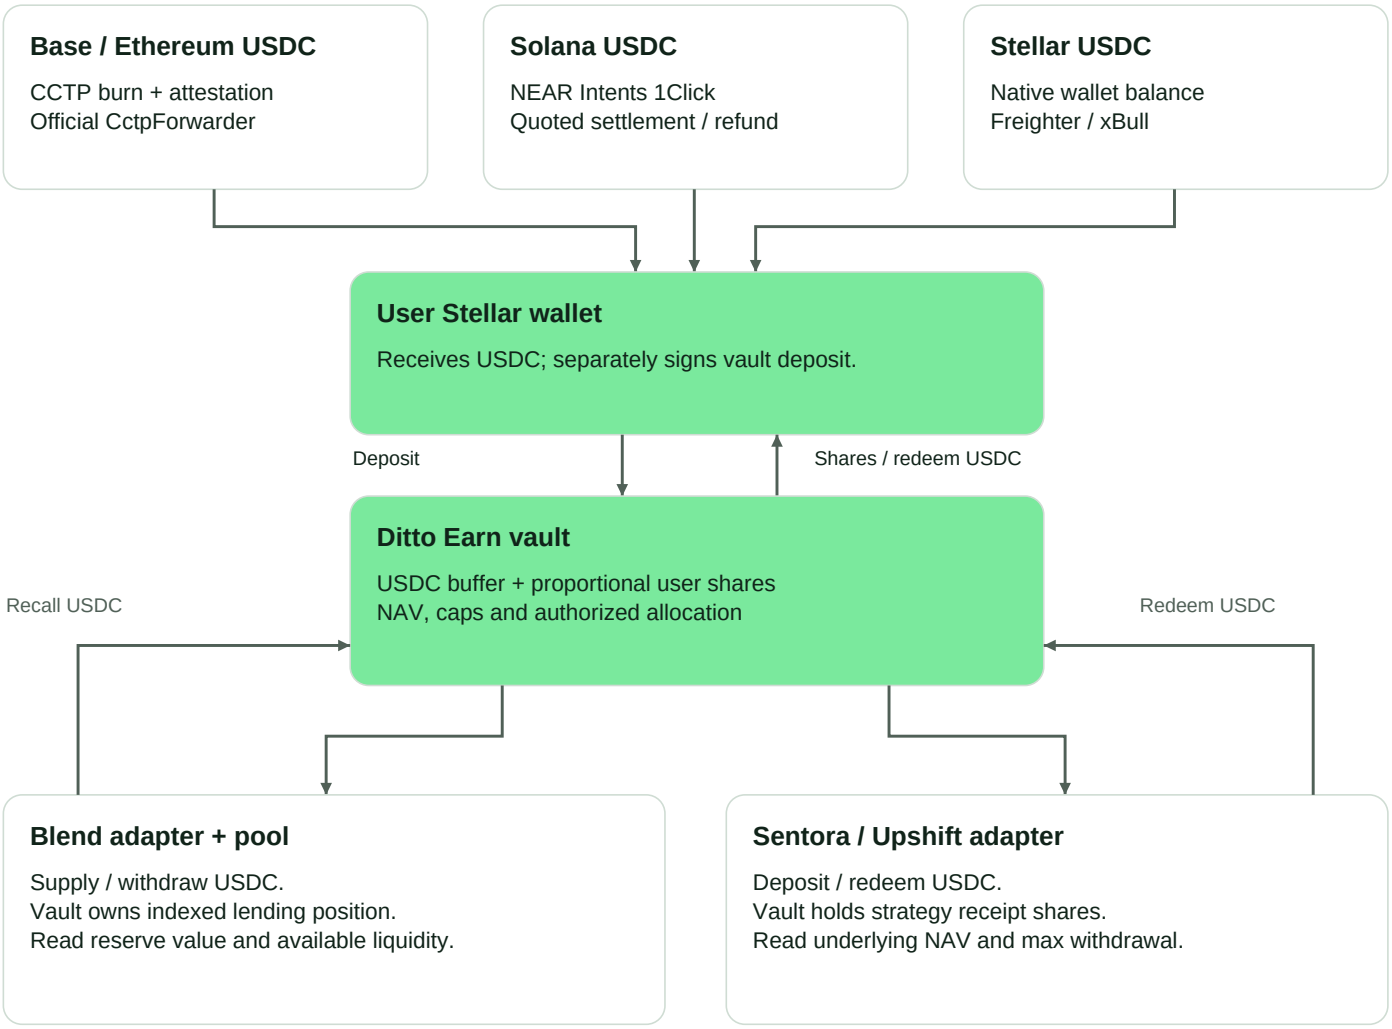
Stellar yield, automated

One USDC vault. Allocation across approved strategies. Reusable operators and SDK for other compatible vaults.

01 DEPOSIT, POSITIONS AND REDEMPTION



Custody: users own Earn shares. Earn holds idle USDC and strategy positions; operators hold no user assets and cannot redirect withdrawals. Sentora manages its underlying backing, which can be deployed outside Stellar. Its contract-reported NAV and available liquidity are separate dependencies.

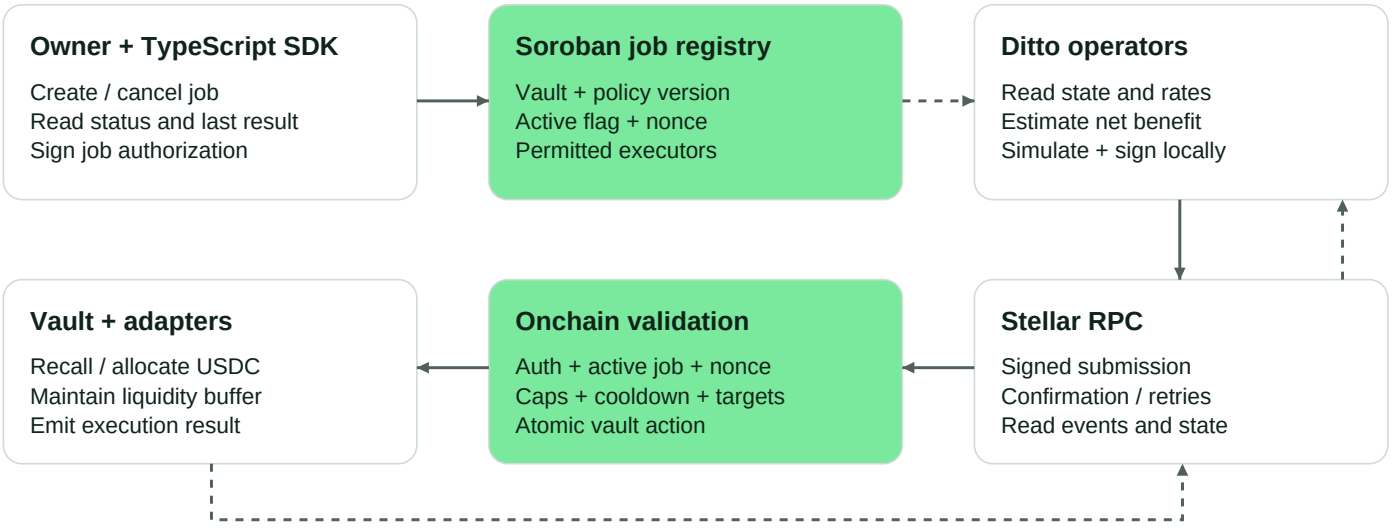
Accounting and exits: NAV = idle USDC + indexed Blend value + underlying-reported USDC value of Sentora shares. Normalize decimals and round conservatively. Redemptions recall available liquidity and revert atomically without burning shares when the requested exit cannot complete.

Launch policy: 100,000 USDC deposit cap; 10% idle target; 20% maximum Sentora weight on new or increased exposure. The vault itself does not borrow. Passive NAV changes can move weights; neither the buffer nor a displayed APY guarantees immediate exits or returns.

Execution with defined limits

Owners authorize supported jobs once. Operators monitor conditions and execute permitted actions through Stellar RPC.

02 JOB LIFECYCLE AND OPERATOR EXECUTION



Solid: authorized calls. Dashed: state / result observation. First valid job nonce wins.

03 CONTROLS THAT MAKE THE FLOW WORK

Allocation Estimate net yield over a configured horizon after fees and movement costs. Blend uses reserve-based estimates; Sentora uses conservative historical returns. Rebalance above the benefit threshold. Contracts enforce limits, not the accuracy of offchain forecasts.

Authority User signatures control deposit/redemption. Executors can only run supported allocation jobs. A 2-of-3 admin multisig enrolls executors and pauses deposits/allocation. Launch strategy addresses and upper limits are fixed; new strategy code uses opt-in migration. Underlying venues retain their own controls.

Continuity Two separately keyed operator instances, nonce protection and cancellation tests. This is failover, not inherited EVM restaking/slashing or a new consensus protocol. Monitor RPC errors, failed jobs, NAV changes, liquidity and Soroban storage lifetime/restoration.

Routing CCTP: forwarder as mintRecipient and destinationCaller, user recipient in hook data; validate account, trustline and 6/7 decimals. Intents: validate asset, recipient, expiry, slippage and refund address. Track settlement and vault deposit separately; resume without duplicate deposit.

$96,000 / 1,200 hours / 16 weeks. Weeks 1-5: vault MVP + Blend. Weeks 6-10: operators, SDK, Sentora adapter and funding routes. Weeks 11-16: review, remediation, capped mainnet and 14-day observation. Deposits open only after external review and all critical/high fixes.
